Introduction

This is the fourth in a series of five manuals:

1. Optimizing software in C++: An optimization guide for Windows, Linux, and Mac platforms.

2. Optimizing subroutines in assembly language: An optimization guide for x86 platforms.

3. The microarchitecture of Intel, AMD, and VIA CPUs: An optimization guide for assembly programmers and compiler makers.

4. Instruction tables: Lists of instruction latencies, throughputs and micro-operation breakdowns for Intel, AMD, and VIA CPUs.

5. Calling conventions for different C++ compilers and operating systems.

The latest versions of these manuals are always available from www.agner.org/optimize. Copyright conditions are listed below.

The present manual contains tables of instruction latencies, throughputs and micro-operation breakdown and other tables for x86 family microprocessors from Intel, AMD, and VIA.

The figures in the instruction tables represent the results of my measurements rather than the official values published by microprocessor vendors. Some values in my tables are higher or lower than the values published elsewhere. The discrepancies can be explained by the following factors:

● My figures are experimental values while figures published by microprocessor vendors may be based on theory or simulations.

● My figures are obtained with a particular test method under particular conditions. It is possible that different values can be obtained under other conditions.

● Some latencies are difficult or impossible to measure accurately, especially for memory access and type conversions that cannot be chained.

● Latencies for moving data from one execution unit to another are listed explicitly in some of my tables while they are included in the general latencies in some tables published by microprocessor vendors.

Most values are the same in all microprocessor modes (real, virtual, protected, 16-bit, 32-bit, 64-bit). Values for far calls and interrupts may be different in different modes. Call gates have not been tested.

Instructions with a LOCK prefix have a long latency that depends on cache organization and possibly RAM speed. If there are multiple processors or cores or direct memory access (DMA) devices, then all locked instructions will lock a cache line for exclusive access, which may involve RAM access. A LOCK prefix typically costs more than a hundred clock cycles, even on single-processor systems. This also applies to the XCHG instruction with a memory operand.

If any text in the pdf version of this manual is unreadable, then please refer to the spreadsheet version.

Definition of terms

Instruction The instruction name is the assembly code for the instruction. Multiple instructions or multiple variants of the same instruction may be joined into the same line. Instructions with and without a 'v' prefix to the name have the same values unless otherwise noted.

Operands Operands can be different types of registers, memory, or immediate constants. Abbreviations used in the tables are: i = immediate constant, r = any general purpose register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x or xmm = 128 bit xmm register, y = 256 bit ymm register, z = 512 bit zmm register, v = any vector register, sr = segment register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Latency The latency of an instruction is the delay that the instruction generates in a dependency chain. The measurement unit is clock cycles. Where the clock frequency is varied dynamically, the figures refer to the core clock frequency. The numbers listed are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity may increase the latencies by possibly more than 100 clock cycles on many processors, except in move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results may give a similar delay. A missing value in the table means that the value has not been measured or that it cannot be measured in a meaningful way.

Some processors have a pipelined execution unit that is smaller than the largest register size so that different parts of the operand are calculated at different times. Assume, for example, that we have a long depencency chain of 128-bit vector instructions running in a fully pipelined 64-bit execution unit with a latency of 4. The lower 64 bits of each operation will be calculated at times 0, 4, 8, 12, 16, etc. And the upper 64 bits of each operation will be calculated at times 1, 5, 9, 13, 17, etc. as shown in the figure below. If we look at one 128-bit instruction in isolation, the latency will be 5. But if we look at a long chain of 128-bit instructions, the total latency will be 4 clock cycles per instruction plus one extra clock cycle in the end. The latency in this case is listed as 4 in the tables because this is the value it adds to a dependency chain.
Reciprocal throughput The throughput is the maximum number of instructions of the same kind that can be executed per clock cycle when the operands of each instruction are independent of the preceding instructions. The values listed are the reciprocals of the throughputs, i.e. the average number of clock cycles per instruction when the instructions are not part of a limiting dependency chain. For example, a reciprocal throughput of 2 for FMUL means that a new FMUL instruction can start executing 2 clock cycles after a previous FMUL. A reciprocal throughput of 0.33 for ADD means that the execution units can handle 3 integer additions per clock cycle.

The reason for listing the reciprocal values is that this makes comparisons between latency and throughput easier. The reciprocal throughput is also called issue latency.

The values listed are for a single thread or a single core. A missing value in the table means that the value has not been measured.

µops   Uop or µop is an abbreviation for micro-operation. Processors with out-of-order cores are capable of splitting complex instructions into µops. For example, a read-modify instruction may be split into a read-µop and a modify-µop. The number of µops that an instruction generates is important when certain bottlenecks in the pipeline limit the number of µops per clock cycle.

Execution unit   The execution core of a microprocessor has several execution units. Each execution unit can handle a particular category of µops, for example floating point additions. The information about which execution unit a particular µop goes to can be useful for two purposes. Firstly, two µops cannot execute simultaneously if they need the same execution unit. And secondly, some processors have a latency of an extra clock cycle when the result of a µop executing in one execution unit is needed as input for a µop in another execution unit.

Execution port   The execution units are clustered around a few execution ports on most Intel processors. Each µop passes through an execution port to get to the right execution unit. An execution port can be a bottleneck because it can handle only one µop at a time. Two µops cannot execute simultaneously if they need the same execution port, even if they are going to different execution units.

Instruction set   This indicates which instruction set an instruction belongs to. The instruction is only available in processors that support this instruction set. The most important instruction sets are listed on the next page. Availability in processors prior to 80386 does not apply for 32-bit and 64-bit operands. Availability in the MMX instruction set does not apply to 128-bit packed integer instructions, which require SSE2. Availability in the SSE instruction set does not apply to double precision floating point instructions, which require SSE2.

32-bit instructions are available in 80386 and later. 64-bit instructions in general purpose registers are available only under 64-bit operating systems. Instructions that use XMM registers (SSE and later), YMM registers (AVX and later), and ZMM registers (AVX512 and later) are only available under operating systems that support these register sets.

How the values were measured

The values in the tables are measured with the use of my own test programs, which are available from www.agner.org/optimize/testp.zip

The time unit for all measurements is CPU clock cycles. It is attempted to obtain the highest clock frequency if the clock frequency is varying with the workload. Many Intel processors have a performance counter named "core clock cycles". This counter gives measurements that are independent of the varying clock frequency. Where no "core clock cycles" counter is available, the "time stamp counter" is used (RDTSC instruction). In cases where this gives inconsistent results (e.g. in AMD Bobcat) it is necessary to make the processor boost the clock frequency by executing a large number of instructions (> 1 million) or turn off the power-saving features in the BIOS setup.

Instruction throughputs are measured with a long sequence of instructions of the same kind, where subsequent instructions use different registers in order to avoid dependence of each instruction on the previous one. The input registers are cleared in the cases where it is impossible to use different registers. The test code is carefully constructed in each case to make sure that no other bottleneck is limiting the throughput than the one that is being measured.

Instruction latencies are measured in a long dependency chain of identical instructions where the output of each instruction is used as input for the next instruction.

The sequence of instructions should be long, but not so long that it doesn't fit into the level-1 code cache. A typical length is 100 instructions of the same type. This sequence is repeated in a loop if a larger number of instructions is desired.

Definition of terms

It is not possible to measure the latency of a memory read or write instruction with software methods. It is only possible to measure the combined latency of a memory write followed by a memory read from the same address. What is measured here is not actually the cache access time, because in most cases the microprocessor is smart enough to make a "store forwarding" directly from the write unit to the read unit rather than waiting for the data to go to the cache and back again. The latency of this store forwarding process is arbitrarily divided into a write latency and a read latency in the tables. But in fact, the only value that makes sense to performance optimization is the sum of the write time and the read time.

A similar problem occurs where the input and the output of an instruction use different types of registers. For example, the MOVD instruction can transfer data between general purpose registers and XMM vector registers. The value that can be measured is the combined latency of data transfer from one type of registers to another type and back again ($A \rightarrow B \rightarrow A$). The division of this latency between the $A \rightarrow B$ latency and the $B \rightarrow A$ latency is sometimes obvious, sometimes based on guesswork, µop counts, indirect evidence, or triangular sequences such as $A \rightarrow B \rightarrow Memory \rightarrow A$. In many cases, however, the division of the total latency between $A \rightarrow B$ latency and $B \rightarrow A$ latency is arbitrary. However, what cannot be measured cannot matter for performance optimization. What counts is the sum of the $A \rightarrow B$ latency and the $B \rightarrow A$ latency, not the individual terms.

The µop counts are usually measured with the use of the performance monitor counters (PMCs) that are built into modern microprocessors. The PMCs for VIA processors are undocumented, and the interpretation of these PMCs is based on experimentation.

The execution ports and execution units that are used by each instruction or µop are detected in different ways depending on the particular microprocessor. Some microprocessors have PMCs that can give this information directly. In other cases it is necessary to obtain this information indirectly by testing whether a particular instruction or µop can execute simultaneously with another instruction/µop that is known to go to a particular execution port or execution unit. On some processors, there is a delay for transmitting data from one execution unit (or cluster of execution units) to another. This delay can be used for detecting whether two different instructions/µops are using the same or different execution units.

Instruction sets

Explanation of instruction sets for x86 processors

x86	This is the name of the common instruction set, supported by all processors in this lineage.
80186	This is the first extension to the x86 instruction set. New integer instructions: PUSH i, PUSHA, POPA, IMUL r,r,i, BOUND, ENTER, LEAVE, shifts and rotates by immediate ≠ 1.
80286	System instructions for 16-bit protected mode.
80386	The eight general purpose registers are extended from 16 to 32 bits. 32-bit addressing. 32-bit protected mode. Scaled index addressing. MOVZX, MOVSX, IMUL r,r, SHLD, SHRD, BT, BTR, BTS, BTC, BSF, BSR, SETcc.
80486	BSWAP. Later versions have CPUID.
x87	This is the floating point instruction set. Supported when a 8087 or later coprocessor is present. Some 486 processors and all processors since Pentium/ K5 have built-in support for floating point instructions without the need for a coprocessor.
80287	FSTSW AX
80387	FPREM1, FSIN, FCOS, FSINCOS.
Pentium	RDTSC, RDPMC.
PPro	Conditional move (CMOV, FCMOV) and fast floating point compare (FCOMI) instructions introduced in Pentium Pro. These instructions are not supported in Pentium MMX, but are supported in all processors with SSE and later.
MMX	Integer vector instructions with packed 8, 16 and 32-bit integers in the 64-bit MMX registers MM0 - MM7, which are aliased upon the floating point stack registers ST(0) - ST(7).
SSE	Single precision floating point scalar and vector instructions in the new 128-bit XMM registers XMM0 - XMM7. PREFETCH, SFENCE, FXSAVE, FXRSTOR, MOVNTQ, MOVNTPS. The use of XMM registers requires operating system support.
SSE2	Double precision floating point scalar and vector instructions in the 128-bit XMM registers XMM0 - XMM7. 64-bit integer arithmetics in the MMX registers. Integer vector instructions with packed 8, 16, 32 and 64-bit integers in the XMM registers. MOVNTI, MOVNTPD, PAUSE, LFENCE, MFENCE.
SSE3	FISTTP, LDDQU, MOVDDUP, MOVSHDUP, MOVSLDUP, ADDSUBPS, ADDSUPPD, HADDPS, HADDPD, HSUBPS, HSUBPD.
SSSE3	(Supplementary SSE3): PSHUFB, PHADDW, PHADDSW, PHADDD, PMADDUBSW, PHSUBW, PHSUBSW, PHSUBD, PSIGNB, PSIGNW, PSIGND, PMULHRSW, PABSB, PABSW, PABSD, PALIGNR.
64 bit	This instruction set is called x86-64, x64, AMD64 or EM64T. It defines a new 64-bit mode with 64-bit addressing and the following extensions: The general purpose registers are extended to 64 bits, and the number of general purpose registers is extended from eight to sixteen. The number of XMM registers is also extended from eight to sixteen, but the number of MMX and ST registers is still eight. Data can be addressed relative to the instruction pointer. There is no way to get access to these extensions in 32-bit mode
	Most instructions that involve segmentation are not available in 64 bit mode. Direct far jumps and calls are not allowed, but indirect far jumps, indirect far calls and far returns are allowed. These are used in system code for switching mode. Segment registers DS, ES, and SS cannot be used. The FS and GS segments and segment prefixes are available in 64 bit mode and are used for addressing thread environment blocks and processor environment blocks

Instruction sets

Instructions not available in 64 bit mode	The following instructions are not available in 64-bit mode: PUSHA, POPA, BOUND, INTO, BCD instructions: AAA, AAS, DAA, DAS, AAD, AAM, undocumented instructions (SALC, ICEBP, 82H alias for 80H opcode), SYSENTER, SYSEXIT, ARPL. On some early Intel processors, LAHF and SAHF are not available in 64 bit mode. Increment and decrement register instructions cannot be coded in the short one-byte opcode form because these codes have been reassigned as REX prefixes. Most instructions that involve segmentation are not available in 64 bit mode. Direct far jumps and calls are not allowed, but indirect far jumps, indirect far calls and far returns are allowed. These are used in system code for switching mode. PUSH CS, PUSH DS, PUSH ES, PUSH SS, POP DS, POP ES, POP SS, LDS and LES instructions are not allowed. CS, DS, ES and SS prefixes are allowed but ignored. The FS and GS segments and segment prefixes are available in 64 bit mode and are used for addressing thread environment blocks and processor environment blocks.
SSE4.1	MPSADBW, PHMINPOSUW, PMULDQ, PMULLD, DPPS, DPPD, BLEND.., PMIN.., PMAX.., ROUND.., INSERT.., EXTRACT.., PMOVSX.., PMOVZX.., PTEST, PCMPEQQ, PACKUSDW, MOVNTDQA
SSE4.2	CRC32, PCMPESTRI, PCMPESTRM, PCMPISTRI, PCMPISTRM, PCMPGTQ, POPCNT.
AES	AESDEC, AESDECLAST, AESENC, AESENCLAST, AESIMC, AESKEYGENASSIST.
CLMUL	PCLMULQDQ.
AVX	The sixteen 128-bit XMM registers are extended to 256-bit YMM registers with room for further extension in the future. The use of YMM registers requires operating system support. Floating point vector instructions are available in 256-bit versions. Almost all previous XMM instructions now have two versions: with and without zero-extension into the full YMM register. The zero-extension versions have three operands in most cases. Furthermore, the following instructions are added in AVX: VBROADCASTSS, VBROADCASTSD, VEXTRACTF128, VINSERTF128, VLDMXCSR, VMASKMOVPS, VMASKMOVPD, VPERMILPD, VPERMIL2PD, VPERMILPS, VPERMIL2PS, VPERM2F128, VSTMXCSR, VZEROALL, VZEROUPPER.
AVX2	Integer vector instructions are available in 256-bit versions. Furthermore, the following instructions are added in AVX2: ANDN, BEXTR, BLSI, BLSMSK, BLSR, BZHI, INVPCID, LZCNT, MULX, PEXT, PDEP, RORX, SARX, SHLX, SHRX, TZCNT, VBROADCASTI128, VBROADCASTSS, VBROADCASTSD, VEXTRACTI128, VGATHERDPD, VGATHERQPD, VGATHERDPS, VGATHERQPS, VPGATHERDD, VPGATHERQD, VPGATHERDQ, VPGATHERQQ, VINSERTI128, VPERM2I128, VPERMD, VPERMPD, VPERMPS, VPERMQ, VPMASKMOVD, VPMASKMOVQ, VPSLLVD, VPSLLVQ, VPSRAVD, VPSRLVD, VPSRLVQ.
FMA3	(FMA): Fused multiply and add instructions: VFMADDxxxPD, VFMADDxxxPS, VFMADDxxxSD, VFMADDxxxSS, VFMADDSUBxxxPD, VFMADDSUBxxxPS, VFMSUBADDxxxPD, VFMSUBADDxxxPS, VFMSUBxxxPD, VFMSUBxxxPS, VFMSUBxxxSD, VFMSUBxxxSS, VFNMADDxxxPD, VFNMADDxxPS, VFNMADDxxxSD, VFNMADDxxxSS, VFNMSUBxxxPD, VFNMSUBxxxPS, VFNMSUBxxxSD, VFNMSUBxxxSS.
FMA4	Same as Intel FMA, but with 4 different operands according to a preliminary Intel specification which is now supported only by some AMD processors. Intel's FMA specification has later been changed to FMA3, which is now also supported by AMD.
MOVBE	MOVBE
POPCNT	POPCNT
PCLMUL	PCLMULQDQ
XSAVE	
XSAVEOPT	
RDRAND	RDRAND

Instruction sets

RDSEED	RDSEED
BMI1	ANDN, BEXTR, BLSI, BLSMSK, BLSR, LZCNT, TXCNT
BMI2	BZHI, MULX, PDEP, PEXT, RORX, SARX, SHRX, SHLX
ADX	ADCX, ADOX, CLAC
AVX512F	The 256-bit YMM registers are extended to 512-bit ZMM registers. The number of vector registers is extended to 32 in 64-bit mode, while there are still only 8 vector registers in 32-bit mode. 8 new vector mask registers k0 – k7. Masked vector instructions. Many new instructions. Single- and double precision floating point vectors are always supported. Other instructions are supported if the various optional AVX512 variants, listed below, are supported as well.
AVX512BW	Vectors of 8-bit and 16-bit integers in ZMM registers.
AVX512DQ	Some additional instructions with vectors of 32-bit and 64-bit integers in ZMM registers.
AVX512VL	The vector operations defined for 512-bit vectors in the various AVX512 subsets, including masked operations, can be applied to 128-bit and 256-bit vectors as well.
AVX512CD	Conflict detection instructions
AVX512ER	Approximate exponential function, reciprocal and reciprocal square root
AVX512PF	Gather and scatter prefetch
SHA	Secure hash algorithm
MPX	Memory protection extensions
SMAP	CLAC, STAC
CVT16	VCVTPH2PS, VCVTPS2PH.
3DNow	(AMD only. Obsolete). Single precision floating point vector instructions in the 64-bit MMX registers. Only available on AMD processors. The 3DNow instructions are: FEMMS, PAVGUSB, PF2ID, PFACC, PFADD, PFCMPEQ/GT/GE, PFMAX, PFMIN, PFRCP/IT1/IT2, PFRSQRT/IT1, PFSUB, PFSUBR, PI2FD, PMULHRW, PREFETCH/W.
3DNowE	(AMD only. Obsolete). PF2IW, PFNACC, PFPNACC, PI2FW, PSWAPD.
PREFETCHW	This instruction has survived from 3DNow and now has its own feature name
PREFETCHWT1	PREFETCHWT1
SSE4A	(AMD only). EXTRQ, INSERTQ, LZCNT, MOVNTSD, MOVNTSS, POPCNT. (POPCNT shared with Intel SSE4.2).
XOP	
	(AMD only. Obsolete). VFRCZPD, VFRCZPS, VFRCZSD, VFRCZSS, VPCMOV, VPCOMB, VPCOMD, VPCOMQ, PCOMW, VPCOMUB, VPCOMUD, VPCOMUQ, VPCOMUW, VPHADDBD, VPHADDBQ, VPHADDBW, VPHADDDQ, VPHADDUBD, VPHADDUBQ, VPHADDUBW, VPHADDUDQ, VPHADDUWD, VPHADDUWQ, VPHADDWD, VPHADDWQ, VPHSUBBW, VPHSUBDQ, VPHSUBWD, VPMACSDD, VPMACSDQH, VPMACSDQL, VPMACSSDD, VPMACSSDQH, VPMACSSDQL, VPMACSSWD, VPMACSSWW, VPMACSWD, VPMACSWW, VPMADCSSWD, VPMADCSWD, VPPERM, VPROTB, VPROTD, VPROTQ, VPROTW, VPSHAB, VPSHAD, VPSHAQ, VPSHAW, VPSHLB, VPSHLD, VPSHLQ, VPSHLW.

Microprocessor versions tested

The tables in this manual are based on testing of the following microprocessors

Processor name	Microarchitecture Code name	Family number (hex)	Model number (hex)	Comment
AMD K7 Athlon		6	6	Step. 2, rev. A5
AMD K8 Opteron		F	5	Stepping A
AMD K10 Opteron		10	2	2350, step. 1
AMD Bulldozer	Bulldozer, Zambezi	15	1	FX-6100, step 2
AMD Piledriver	Piledriver	15	2	FX-8350, step 0. And others
AMD Steamroller	Steamroller, Kaveri	15	30	A10-7850K, step 1
AMD Excavator	Bristol Ridge	15	65	A10-9700E, step 1
AMD Ryzen	Zen 1	17	1	Ryzen 7 1800X, step. 1
AMD Ryzen 3700	Zen 2	17	71	Ryzen 7 3700X, step. 0
AMD Ryzen 5000	Zen 3	19	21	Ryzen 7 5800X, step. 0
AMD Ryzen 9	Zen 4	19	61	Ryzen 9 7900X, step. 2
AMD Bobcat	Bobcat	14	1	E350, step. 0
AMD Kabini	Jaguar	16	0	A4-5000, step 1
Intel Pentium	P5	5	2	
Intel Pentium MMX	P5	5	4	Stepping 4
Intel Pentium II	P6	6	6	
Intel Pentium III	P6	6	7	
Intel Pentium 4	Netburst	F	2	Stepping 4, rev. B0
Intel Pentium 4 EM64T	Netburst, Prescott	F	4	Xeon. Stepping 1
Intel Pentium M	Dothan	6	D	Stepping 6, rev. B1
Intel Core Duo	Yonah	6	E	Not fully tested
Intel Core 2 (65 nm)	Merom	6	F	T5500, Step. 6, rev. B2
Intel Core 2 (45 nm)	Wolfdale	6	17	E8400, Step. 6
Intel Core i7	Nehalem	6	1A	i7-920, Step. 5, rev. D0
Intel 2nd gen. Core	Sandy Bridge	6	2A	i5-2500, Step 7
Intel 3rd gen. Core	Ivy Bridge	6	3A	i7-3770K, Step 9
Intel 4th gen. Core	Haswell	6	3C	i7-4770K, step. 3
Intel 5th gen. Core	Broadwell	6	56	D1540, step 2
Intel 6th gen. Core	Skylake	6	5E	Step. 3
Intel 7th gen. Core	Skylake-X, Cascade L.	6	55	Step. 4
Intel 9th gen. Core	Coffee Lake	6	9E	Step. B
Intel 10th gen. Core	Cannon Lake	6	66	Step. 3
Intel 10th gen. Core	Ice Lake	6	7E	Step. 5
Intel 11th gen. Core	Tiger Lake	6	8C	Step. 1
Intel Atom 330	Diamondville	6	1C	Step. 2
Intel Bay Trail	Silvermont	6	37	Step. 3
Intel Apollo Lake	Goldmont	6	5C	Step. 9
Intel Gemini Lake	Goldmont Plus	6	7A	Step. 1
Intel Jasper Lake	Tremont	6	9C	Step. 0
Intel Xeon Phi	Knights Landing	6	57	Step. 1
VIA Nano L2200		6	F	Step. 2
VIA Nano L3050	Isaiah	6	F	Step. 8 (prerelease sample)

AMD K7
List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, xmm = 128 bit xmm register, sr = segment register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers. Instructions with more than 2 macro-operations use microcode.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latency listed does not include the memory operand where the operand is listed as register or memory (r/m).

Reciprocal throughput: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution unit: Indicates which execution unit is used for the macro-operations. ALU means any of the three integer ALU's. ALU0_1 means that ALU0 and ALU1 are both used. AGU means any of the three integer address generation units. FADD means floating point adder unit. FMUL means floating point multiplier unit. FMISC means floating point store and miscellaneous unit. FA/M means FADD or FMUL is used. FANY means any of the three floating point units can be used. Two macro-operations can execute simultaneously if they go to different execution units.

Integer instructions

Instruction	Operands	Ops	Latency	Reciprocal throughput	Execution unit	Notes
Move instructions						
MOV	r,r	1	1	1/3	ALU	
MOV	r,i	1	1	1/3	ALU	
MOV	r8,m8	1	4	1/2	ALU, AGU	Any addr. mode. Add 1 clk if code segment base ≠ 0
MOV	r16,m16	1	4	1/2	ALU, AGU	do.
MOV	r32,m32	1	3	1/2	AGU	do.
MOV	m8,r8H	1	8	1/2	AGU	AH, BH, CH, DH
MOV	m8,r8L	1	2	1/2	AGU	Any other 8-bit register
MOV	m16/32,r	1	2	1/2	AGU	Any addressing mode
MOV	m,i	1	2	1/2	AGU	
MOV	r,sr	1	2	1		
MOV	sr,r/m	6	9-13	8		
MOVZX, MOVSX	r,r	1	1	1/3	ALU	
MOVZX, MOVSX	r,m	1	4	1/2	ALU, AGU	

CMOVcc	r,r	1	1	1/3	ALU	
CMOVcc	r,m	1		1/2	ALU, AGU	
XCHG	r,r	3	2	1	ALU	
XCHG	r,m	3	16	16	ALU, AGU	Timing depends on hw
XLAT		2	5		ALU, AGU	
PUSH	r	1		1	ALU, AGU	
PUSH	i	1		1	ALU, AGU	
PUSH	m	2		1	ALU, AGU	
PUSH	sr	2		1	ALU, AGU	
PUSHF(D)		1		1	ALU, AGU	
PUSHA(D)		9		4	ALU, AGU	
POP	r	2		1	ALU, AGU	
POP	m	3		1	ALU, AGU	
POP	DS/ES/FS/GS	6		10	ALU, AGU	
POP	SS	9		18	ALU, AGU	
POPF(D)		2		1	ALU, AGU	
POPA(D)		9		4	ALU, AGU	
LEA	r16,[m]	2	3	1	AGU	Any addr. size
LEA	r32,[m]	1	2	1/3	AGU	Any addr. size
LAHF		4	3	2	ALU	
SAHF		2	2	2	ALU	
SALC		1	1	1	ALU	
LDS, LES, ...	r,m	10		9		
BSWAP	r	1	1	1/3	ALU	

Arithmetic instructions

ADD, SUB	r,r/i	1	1	1/3	ALU	
ADD, SUB	r,m	1	1	1/2	ALU, AGU	
ADD, SUB	m,r	1	7	2.5	ALU, AGU	
ADC, SBB	r,r/i	1	1	1/3	ALU	
ADC, SBB	r,m	1	1	1/2	ALU, AGU

AMD K8

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, xmm = 128 bit xmm register, sr = segment register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers. Instructions with more than 2 macro-operations use microcode.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latency listed does not include the memory operand where the operand is listed as register or memory (r/m).

Reciprocal throughput: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution unit: Indicates which execution unit is used for the macro-operations. ALU means any of the three integer ALU's. ALU0_1 means that ALU0 and ALU1 are both used. AGU means any of the three integer address generation units. FADD means floating point adder unit. FMUL means floating point multiplier unit. FMISC means floating point store and miscellaneous unit. FA/M means FADD or FMUL is used. FANY means any of the three floating point units can be used. Two macro-operations can execute simultaneously if they go to different execution units.

AMD K10
List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, xmm = 128 bit xmm register, sr = segment register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers. Instructions with more than 2 macro-operations use microcode.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latency listed does not include the memory operand where the operand is listed as register or memory (r/m).

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution unit: Indicates which execution unit is used for the macro-operations. ALU means any of the three integer ALU's. ALU0_1 means that ALU0 and ALU1 are both used. AGU means any of the three integer address generation units. FADD means floating point adder unit. FMUL means floating point multiplier unit. FMISC means floating point store and miscellaneous unit. FA/M means FADD or FMUL is used. FANY means any of the three floating point units can be used. Two macro-operations can execute simultaneously if they go to different execution units.

Thank you to Xucheng Tang for doing the measurements on the K10.

AMD Bulldozer
List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers. Instructions with more than 2 macro-operations use microcode.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m).

Reciprocal throughput: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
Integer pipes:
EX0: integer ALU, division
EX1: integer ALU, multiplication, jump
EX01: can use either EX0 or EX1
AG01: address generation unit 0 or 1
Floating point and vector pipes:
P0: floating point add, mul, div, convert, shuffle, shift
P1: floating point add, mul, div, shuffle, shift
P2: move, integer add, boolean
P3: move, integer add, boolean, store
P01: can use either P0 or P1
P23: can use either P2 or P3
Two macro-operations can execute simultaneously if they go to different execution pipes

Domain: Tells which execution unit domain is used:
ivec: integer vector execution unit.
fp: floating point execution unit.
fma: floating point multiply/add subunit.
inherit: the output operand inherits the domain of the input operand.
ivec/fma means the input goes to the ivec domain and the output comes from the fma domain.
There is an additional latency of 1 clock cycle if the output of an ivec instruction goes to the input of a fp or fma instruction, and when the output of a fp or fma instruction goes to the input of an ivec or store instruction. There is no latency between the fp and fma units. All other latencies after memory load and before memory store instructions are included in the latency counts.
An fma instruction has a latency of 5 if the output goes to another fma instruction, 6 if the output goes to an fp instuction, and 6+1 if the output goes to an ivec or store instruction.

AMD Piledriver

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers. Instructions with more than 2 macro-operations use microcode.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m).

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
Integer pipes:
EX0: integer ALU, division
EX1: integer ALU, multiplication, jump
EX01: can use either EX0 or EX1
AG01: address generation unit 0 or 1
Floating point and vector pipes:
P0: floating point add, mul, div, convert, shuffle, shift
P1: floating point add, mul, div, shuffle, shift
P2: move, integer add, boolean
P3: move, integer add, boolean, store
P01: can use either P0 or P1
P23: can use either P2 or P3
Two macro-operations can execute simultaneously if they go to different execution pipes

Domain: Tells which execution unit domain is used:
ivec: integer vector execution unit.
fp: floating point execution unit.
fma: floating point multiply/add subunit.
inherit: the output operand inherits the domain of the input operand.
ivec/fma means the input goes to the ivec domain and the output comes from the fma domain.
There is an additional latency of 1 clock cycle if the output of an ivec instruction goes to the input of a fp or fma instruction, and when the output of a fp or fma instruction goes to the input of an ivec or store instruction. There is no latency between the fp and fma units. All other latencies after memory load and before memory store instructions are included in the latency counts.
An fma instruction has a latency of 5 if the output goes to another fma instruction, 6 if the output goes to an fp instuction, and 6+1 if the output goes to an ivec or store instruction.

AMD Steamroller

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers. Instructions with more than 2 macro-operations use microcode.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m).

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
Integer pipes:
EX0: integer ALU, division
EX1: integer ALU, multiplication, jump
EX01: can use either EX0 or EX1
AG01: address generation unit 0 or 1
Floating point and vector pipes:
P0: floating point add, mul, div. Integer add, mul, bool
P1: floating point add, mul, div. Shuffle, shift, pack
P2: Integer add. Bool, store
P01: can use either P0 or P1
P02: can use either P0 or P2
Two macro-operations can execute simultaneously if they go to different execution pipes

Domain: Tells which execution unit domain is used:
ivec: integer vector execution unit.
fp: floating point execution unit.
fma: floating point multiply/add subunit.
inherit: the output operand inherits the domain of the input operand.
ivec/fma means the input goes to the ivec domain and the output comes from the fma domain.
There is an additional latency of 1 clock cycle if the output of an ivec instruction goes to the input of a fp or fma instruction, and when the output of a fp or fma instruction goes to the input of an ivec or store instruction. There is no latency between the fp and fma units. All other latencies after memory load and before memory store instructions are included in the latency counts.
An fma instruction has a latency of 5 if the output goes to another fma instruction, 6 if the output goes to an fp instuction, and 6+1 if the output goes to an ivec or store instruction.

AMD Excavator
List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers. Instructions with more than 2 macro-operations use microcode.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m). The numbers are approximate.

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
Integer pipes:
EX0: integer ALU, division
EX1: integer ALU, multiplication, jump
EX01: can use either EX0 or EX1
AG01: address generation unit 0 or 1
Floating point and vector pipes:
P0: floating point add, mul, div. Integer add, mul, bool
P1: floating point add, mul, div. Shuffle, shift, pack
P2: Integer add. Bool, store
P01: can use either P0 or P1
P02: can use either P0 or P2
Two macro-operations can execute simultaneously if they go to different execution pipes

Domain: Tells which execution unit domain is used:
ivec: integer vector execution unit.
fp: floating point execution unit.
fma: floating point multiply/add subunit.
inherit: the output operand inherits the domain of the input operand.
ivec/fma means the input goes to the ivec domain and the output comes from the fma domain.
There is an additional latency of 1 clock cycle if the output of an ivec instruction goes to the input of a fp or fma instruction, and when the output of a fp or fma instruction goes to the input of an ivec or store instruction. There is no latency between the fp and fma units. All other latencies after memory load and before memory store instructions are included in the latency counts.
An fma instruction has a latency of 5 if the output goes to another fma instruction, 6 if the output goes to an fp instuction, and 6+1 if the output goes to an ivec or store instruction.

Integer instructions

AMD Zen 1

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m).

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
P0: Floating point and vector pipe 0
P1: Floating point and vector pipe 1
P2: Floating point and vector pipe 2
P3: Floating point and vector pipe 3
P0 P1: Uses both P0 and P1
P01: Uses either P0 and P1
Where no unit is specified, it uses one or more integer pipe or address generation units.
Two micro-operations can execute simultaneously if they go to different execution pipes

Domain: Tells which execution unit domain is used:
ivec: integer vector execution unit.
fp: floating point execution unit.
inherit: the output operand inherits the domain of the input operand.
There is an additional latency of 1 clock cycle if the output of an ivec instruction goes to the input of a fp instruction, and when the output of a fp instruction goes to the input of an ivec instruction. All other latencies after memory load and before memory store instructions are included in the latency counts.

Integer instructions

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Similar instructions with or without V name prefix and with two or three operands behave the same unless otherwise noted.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, v = any vector register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m).

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
P0: Floating point and vector pipe 0
P1: Floating point and vector pipe 1
P2: Floating point and vector pipe 2
P3: Floating point and vector pipe 3
P0 P1: Uses both P0 and P1
P01: Uses either P0 and P1
Where no unit is specified, it uses one or more integer pipe or address generation units.
Two micro-operations can execute simultaneously if they go to different execution pipes

Domain: Tells which execution unit domain is used:
ivec: integer vector execution unit.
fp: floating point execution unit.
inherit: the output operand inherits the domain of the input operand.
There is an additional latency of 1 clock cycle if the output of an ivec instruction goes to the input of a fp instruction, and when the output of a fp instruction goes to the input of an ivec instruction. All other latencies after memory load and before memory store instructions are included in the latency counts.

Integer instructions

AMD Zen 3

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Similar instructions with or without V name prefix and with two or three operands behave the same unless otherwise noted.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, v = any vector register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m).

Reciprocal throughput: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
P0: Floating point and vector pipe 0
P1: Floating point and vector pipe 1
P2: Floating point and vector pipe 2
P3: Floating point and vector pipe 3
P0 P1: Uses both P0 and P1
P01: Uses either P0 and P1
Where no unit is specified, it may use one or more integer pipe or address generation units.
Two micro-operations can execute simultaneously if they go to different execution pipes

Domain: Tells which execution unit domain is used:
ivec: integer vector execution unit.
fp: floating point execution unit.
inherit: the output operand inherits the domain of the input operand.
There is an additional latency of 1 clock cycle if the output of an ivec instruction goes to the input of a fp instruction, and when the output of a fp instruction goes to the input of an ivec instruction. All other latencies after memory load and before memory store instructions are included in the latency counts.

AMD Zen 4

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Similar instructions with or without V name prefix and with two or three operands behave the same unless otherwise noted.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, z = 512 bit zmm register, xy = vector register no bigger than 256 bits, v = any vector register, k = mask register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of macro-operations issued from instruction decoder to schedulers.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. The latency listed does not include the memory operand where the listing for register and memory operand are joined (r/m).

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/3 indicates that the execution units can handle 3 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe or unit is used for the macro-operations:
P0: Floating point and vector pipe 0
P1: Floating point and vector pipe 1
P2: Floating point and vector pipe 2
P3: Floating point and vector pipe 3
P0 P1: Uses both P0 and P1
P01: Uses either P0 and P1
Where no unit is specified, it may use one or more integer pipe or address generation units.
Two micro-operations can execute simultaneously if they go to different execution pipes

AMD Bobcat

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, xmm = 128 bit xmm register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of micro-operations issued from instruction decoder to schedulers. Instructions with more than 2 micro-operations are micro-coded.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latencies listed do not include memory operands where the operand is listed as register or memory (r/m).

The clock frequency varies dynamically, which makes it difficult to measure latencies. The values listed are measured after the execution of millions of similar instructions, assuming that this will make the processor boost the clock frequency to the highest possible value.

Reciprocal through-put: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/2 indicates that the execution units can handle 2 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe is used for the micro-operations. I0 means integer pipe 0. I0/1 means integer pipe 0 or 1. FP0 means floating point pipe 0 (ADD). FP1 means floating point pipe 1 (MUL). FP0/1 means either one of the two floating point pipes. Two micro-operations can execute simultaneously if they go to different execution pipes.

Integer instructions

AMD Jaguar

List of instruction timings and macro-operation breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, xmm = 128 bit xmm register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

Ops: Number of micro-operations issued from instruction decoder to schedulers. Instructions with more than 2 micro-operations are micro-coded.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latencies listed do not include memory operands where the operand is listed as register or memory (r/m).

The clock frequency varies dynamically, which makes it difficult to measure latencies. The values listed are measured after the execution of millions of similar instructions, assuming that this will make the processor boost the clock frequency to the highest possible value.

Reciprocal throughput: This is also called issue latency. This value indicates the average number of clock cycles from the execution of an instruction begins to a subsequent independent instruction of the same kind can begin to execute. A value of 1/2 indicates that the execution units can handle 2 instructions per clock cycle in one thread. However, the throughput may be limited by other bottlenecks in the pipeline.

Execution pipe: Indicates which execution pipe is used for the micro-operations. I0 means integer pipe 0. I0/1 means integer pipe 0 or 1. FP0 means floating point pipe 0 (ADD). FP1 means floating point pipe 1 (MUL). FP0/1 means either one of the two floating point pipes. Two micro-operations can execute simultaneously if they go to different execution pipes.

Intel Pentium and Pentium MMX

List of instruction timings

Explanation of column headings:

Operands	r = register, accum = al, ax or eax, m = memory, i = immediate data, sr = segment register, m32 = 32 bit memory operand, etc.
Clock cycles	The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably.
Pairability	u = pairable in u-pipe, v = pairable in v-pipe, uv = pairable in either pipe, np = not pairable.

Notes:

a	This instruction has a 0FH prefix which takes one clock cycle extra to decode on a P1 unless preceded by a multi-cycle instruction.
b	versions with FS and GS have a 0FH prefix. see note a.
c	versions with SS, FS, and GS have a 0FH prefix. see note a.
d	versions with two operands and no immediate have a 0FH prefix, see note a.
e	high values are for mispredicted jumps/branches.
f	only pairable if register is AL, AX or EAX.
g	add one clock cycle for decoding the repeat prefix unless preceded by a multi-cycle instruction (such as CLD).
h	pairs as if it were writing to the accumulator.
i	9 if SP divisible by 4 (imperfect pairing).
j	on P1: 6 in privileged or real mode; 11 in non-privileged; error in virtual mode. On PMMX: 8 and 13 clocks respectively.

Floating point instructions (Pentium and Pentium MMX)

Explanation of column headings

Operands	r = register, m = memory, m32 = 32-bit memory operand, etc.
Clock cycles	The numbers are minimum values. Cache misses, misalignment, denormal operands, and exceptions may increase the clock counts considerably.
Pairability	+ = pairable with FXCH, np = not pairable with FXCH.
i-ov	Overlap with integer instructions. i-ov = 4 means that the last four clock cycles can overlap with subsequent integer instructions.
fp-ov	Overlap with floating point instructions. fp-ov = 2 means that the last two clock cycles can overlap with subsequent floating point instructions. (WAIT is considered a floating point instruction here)

FRSTOR	m	70-95	np	0	0
WAIT		1	np	0	0

Notes:

m	The value to store is needed one clock cycle in advance.
n	1 if the overlapping instruction is also an FMUL.
o	Cannot overlap integer multiplication instructions.
p	FDIV takes 19, 33, or 39 clock cycles for 24, 53, and 64 bit precision re-spectively. FIDIV takes 3 clocks more. The precision is defined by bit 8-9 of the floating point control word.
q	The first 4 clock cycles can overlap with preceding integer instructions.
r	Clock counts are typical. Trivial cases may be faster, extreme cases may be slower.
s	May be up to 3 clocks more when output needed for FST, FCHS, or FABS.

MMX instructions (Pentium MMX)

A list of MMX instruction timings is not needed because they all take one clock cycle, except the MMX multiply instructions which take 3. MMX multiply instructions can be pipelined to yield a throughput of one multiplication per clock cycle.
The EMMS instruction takes only one clock cycle, but the first floating point instruction after an EMMS takes approximately 58 clocks extra, and the first MMX instruction after a floating point instruction takes approximately 38 clocks extra. There is no penalty for an MMX instruction after EMMS on the PMMX.

There is no penalty for using a memory operand in an MMX instruction because the MMX arithmetic unit is one step later in the pipeline than the load unit. But the penalty comes when you store data from an MMX register to memory or to a 32-bit register: The data have to be ready one clock cycle in advance. This is analogous to the floating point store instructions.
All MMX instructions except EMMS are pairable in either pipe. Pairing rules for MMX instructions are de-scribed in manual 3: "The microarchitecture of Intel, AMD and VIA CPUs".

Intel Pentium II and Pentium III
List of instruction timings and µop breakdown

Explanation of column headings:

Operands:	i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.
µops:	The number of µops that the instruction generates for each execution port.
p0:	Port 0: ALU, etc.
p1:	Port 1: ALU, jumps
p01:	Instructions that can go to either port 0 or 1, whichever is vacant first.
p2:	Port 2: load data, etc.
p3:	Port 3: address generation for store
p4:	Port 4: store data
Latency:	This is the delay that the instruction generates in a dependency chain. (This is not the same as the time spent in the execution unit. Values may be inaccurate in situations where they cannot be measured exactly, especially with memory operands). The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays by 50-150 clocks, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.
Reciprocal throughput:	The average number of clock cycles per instruction for a series of independent instructions of the same kind.

Notes:

e)   Not pipelined

f)   FXCH generates 1 µop that is resolved by register renaming without going to any port.

g)   FMUL uses the same circuitry as integer multiplication. Therefore, the combined throughput of mixed floating point and integer multiplications is 1 FMUL + 1 IMUL per 3 clock cycles.

h)   FDIV latency depends on precision specified in control word: 64 bits precision gives latency 38, 53 bits precision gives latency 32, 24 bits precision gives latency 18. Division by a power of 2 takes 9 clocks. Reciprocal throughput is 1/(latency-1).

i)   Faster for lower precision.

PSADBW d)	mm,m64	2		1	1			6	2

Notes:

d)   P3 only.

k)   The delay can be hidden by inserting other instructions between EMMS and any subsequent floating point instruction.

Intel Pentium M, Core Solo and Core Duo
List of instruction timings and µop breakdown

Explanation of column headings:

Operands:	i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.
µops fused domain:	The number of µops at the decode, rename, allocate and retirement stages in the pipeline. Fused µops count as one.
µops unfused domain:	The number of µops for each execution port. Fused µops count as two.
p0:	Port 0: ALU, etc.
p1:	Port 1: ALU, jumps
p01:	Instructions that can go to either port 0 or 1, whichever is vacant first.
p2:	Port 2: load data, etc.
p3:	Port 3: address generation for store
p4:	Port 4: store data
Latency:	This is the delay that the instruction generates in a dependency chain. (This is not the same as the time spent in the execution unit. Values may be inaccurate in situations where they cannot be measured exactly, especially with memory operands). The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays by 50-150 clocks, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.
Reciprocal throughput:	The average number of clock cycles per instruction for a series of independent instructions of the same kind.

CPUID		38-59	38-59						ca. 130	
RDTSC		13	13							42

Notes:

a) Faster under certain conditions: see manual 3: "The microarchitecture of Intel, AMD and VIA CPUs".

b) Has an implicit LOCK prefix.

c) High values are typical, low values are for round divisors. Core Solo/Duo is more efficient than Pentium M in cases with round values that allow an early-out algorithm.

Notes:

c)	High values are typical, low values are for round divisors.
g)	SSE3 instruction only available on Core Solo and Core Duo.
j)	Also uses some execution units under port 1.

Intel Core 2 (Merom, 65nm)
List of instruction timings and µop breakdown

Explanation of column headings:

Operands:	i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, mm/x = mmx or xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.
µops fused domain:	The number of µops at the decode, rename, allocate and retirement stages in the pipeline. Fused µops count as one.
µops unfused domain:	The number of µops for each execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if the sum of the numbers listed under p015 + p2 + p3 + p4 exceeds the number listed under µops fused domain. An x under p0, p1 or p5 means that at least one of the µops listed under p015 can optionally go to this port. For example, a 1 under p015 and an x under p0 and p5 means one µop which can go to either port 0 or port 5, whichever is vacant first. A value listed under p015 but nothing under p0, p1 and p5 means that it is not known which of the three ports these µops go to.
p015:	The total number of µops going to port 0, 1 and 5.
p0:	The number of µops going to port 0 (execution units).
p1:	The number of µops going to port 1 (execution units).
p5:	The number of µops going to port 5 (execution units).
p2:	The number of µops going to port 2 (memory read).
p3:	The number of µops going to port 3 (memory write address).
p4:	The number of µops going to port 4 (memory write data).
Unit:	Tells which execution unit cluster is used. An additional delay of 1 clock cycle is generated if a register written by a µop in the integer unit (int) is read by a µop in the floating point unit (float) or vice versa. flt→int means that an instruction with multiple µops receive the input in the float unit and delivers the output in the int unit. Delays for moving data between different units are included under latency when they are unavoidable. For example, movd eax,xmm0 has an extra 1 clock delay for moving from the XMM-integer unit to the general purpose integer unit. This is included under latency because it occurs regardless of which instruction comes next. Nothing listed under unit means that additional delays are either unlikely to occur or unavoidable and therefore included in the latency figure.
Latency:	This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.
Reciprocal throughput:	The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Notes:

a)	Applies to all addressing modes
b)	Has an implicit LOCK prefix.
c)	Low values are for small results, high values for high results.
e)	See manual 3: "The microarchitecture of Intel, AMD and VIA CPUs" for restrictions on macro-op fusion.
i)	Not available in 64 bit mode.

Notes:

d)   Round divisors give low values.

g)   SSE3 instruction set.

Intel Core 2 (Wolfdale, 45nm)

List of instruction timings and µop breakdown

Explanation of column headings:

Operands:	i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, mm/x = mmx or xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.
µops fused domain:	The number of µops at the decode, rename, allocate and retirement stages in the pipeline. Fused µops count as one.
µops unfused domain:	The number of µops for each execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if the sum of the numbers listed under p015 + p2 + p3 + p4 exceeds the number listed under µops fused domain. An x under p0, p1 or p5 means that at least one of the µops listed under p015 can optionally go to this port. For example, a 1 under p015 and an x under p0 and p5 means one µop which can go to either port 0 or port 5, whichever is vacant first. A value listed under p015 but nothing under p0, p1 and p5 means that it is not known which of the three ports these µops go to.
p015:	The total number of µops going to port 0, 1 and 5.
p0:	The number of µops going to port 0 (execution units).
p1:	The number of µops going to port 1 (execution units).
p5:	The number of µops going to port 5 (execution units).
p2:	The number of µops going to port 2 (memory read).
p3:	The number of µops going to port 3 (memory write address).
p4:	The number of µops going to port 4 (memory write data).
Unit:	Tells which execution unit cluster is used. An additional delay of 1 clock cycle is generated if a register written by a µop in the integer unit (int) is read by a µop in the floating point unit (float) or vice versa. flt→int means that an instruction with multiple µops receive the input in the float unit and delivers the output in the int unit. Delays for moving data between different units are included under latency when they are unavoidable. For example, movd eax,xmm0 has an extra 1 clock delay for moving from the XMM-integer unit to the general purpose integer unit. This is included under latency because it occurs regardless of which instruction comes next. Nothing listed under unit means that additional delays are either unlikely to occur or unavoidable and therefore included in the latency figure.
Latency:	This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.
Reciprocal throughput:	The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

RDTSC		13								32
RDPMC		23								54

Notes:

a)	Applies to all addressing modes
b)	Has an implicit LOCK prefix.
c)	Low values are for small results, high values for high results. The reciprocal throughput is only slightly less than the latency.
e)	See manual 3: "The microarchitecture of Intel, AMD and VIA CPUs" for restrictions on macro-op fusion.
i)	Not available in 64 bit mode.

Notes:

d)	Round divisors or low precision give low values.
f)	Resolved by register renaming. Generates no µops in the unfused domain.
g)	SSE3 instruction set.

Notes:

d) Round divisors give low values.

g) SSE3 instruction set.

Intel Nehalem
List of instruction timings and μop breakdown

Explanation of column headings:

Operands:	i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, mm/x = mmx or xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.
μops fused domain:	The number of μops at the decode, rename, allocate and retirement stages in the pipeline. Fused μops count as one.
μops unfused domain:	The number of μops for each execution port. Fused μops count as two. Fused macro-ops count as one. The instruction has μop fusion if the sum of the numbers listed under p015 + p2 + p3 + p4 exceeds the number listed under μops fused domain. An x under p0, p1 or p5 means that at least one of the μops listed under p015 can optionally go to this port. For example, a 1 under p015 and an x under p0 and p5 means one μop which can go to either port 0 or port 5, whichever is vacant first. A value listed under p015 but nothing under p0, p1 and p5 means that it is not known which of the three ports these μops go to.
p015:	The total number of μops going to port 0, 1 and 5.
p0:	The number of μops going to port 0 (execution units).
p1:	The number of μops going to port 1 (execution units).
p5:	The number of μops going to port 5 (execution units).
p2:	The number of μops going to port 2 (memory read).
p3:	The number of μops going to port 3 (memory write address).
p4:	The number of μops going to port 4 (memory write data).
Domain:	Tells which execution unit domain is used: "int" = integer unit (general purpose registers), "ivec" = integer vector unit (SIMD), "fp" = floating point unit (XMM and x87 floating point). An additional "bypass delay" is generated if a register written by a μop in one domain is read by a μop in another domain. The bypass delay is 1 clock cycle between the "int" and "ivec" units, and 2 clock cycles between the "int" and "fp", and between the "ivec" and "fp" units.
	The bypass delay is indicated under latency only where it is unavoidable because either the source operand or the destination operand is in an unnatural domain such as a general purpose register (e.g. eax) in the "ivec" domain. For example, the PEXTRW instruction executes in the "int" domain. The source operand is an xmm register and the destination operand is a general purpose register. The latency for this instruction is indicated as 2+1, where 2 is the latency of the instruction itself and 1 is the bypass delay, assuming that the xmm operand is most likely to come from the "ivec" domain. If the xmm operand comes from the "fp" domain then the bypass delay will be 2 rather than one. The flags register can also have a bypass delay. For example, the COMISS instruction (floating point compare) executes in the "fp" domain and returns the result in the integer flags. Almost all instructions that read these flags execute in the "int" domain. Here the latency is indicated as 1+2, where 1 is the latency of the instruction itself and 2 is the bypass delay from the "fp" domain to the "int" domain.
	The bypass delay from the memory read unit to any other unit and from any unit to the memory write unit are included in the latency figures in the table. Where the domain is not listed, the bypass delays are either unlikely to occur or unavoidable and therefore included in the latency figure.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.

Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Integer instructions

Notes:

a)	Applies to all addressing modes
b)	Has an implicit LOCK prefix.
c)	Low values are for small results, high values for high results.
e)	See manual 3: "The microarchitecture of Intel, AMD and VIA CPUs" for restrictions on macro-op fusion.
i)	Not available in 64 bit mode.
ℓ)	SSE4.2 instruction set.

Notes:

g) SSE3 instruction set.

Intel Sandy Bridge

List of instruction timings and µop breakdown

Explanation of column headings:

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, y = 256 bit ymm register, same = same register for both operands. m = memory operand, m32 = 32-bit memory operand, etc.

µops fused domain: The number of µops at the decode, rename, allocate and retirement stages in the pipeline. Fused µops count as one.

µops unfused domain: The number of µops for each execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if the sum of the numbers listed under p015 + p23 + p4 exceeds the number listed under µops fused domain. A number indicated as 1+ under a read or write port means a 256-bit read or write operation using two clock cycles for handling 128 bits each cycle. The port cannot receive another read or write µop in the second clock cycle, but a read port can receive an address-calculation µop in the second clock cycle. An x under p0, p1 or p5 means that at least one of the µops listed under p015 can optionally go to this port. For example, a 1 under p015 and an x under p0 and p5 means one µop which can go to either port 0 or port 5, whichever is vacant first. A value listed under p015 but nothing under p0, p1 and p5 means that it is not known which of the three ports these µops go to.

p015: The total number of µops going to port 0, 1 and 5.
p0: The number of µops going to port 0 (execution units).
p1: The number of µops going to port 1 (execution units).
p5: The number of µops going to port 5 (execution units).
p23: The number of µops going to port 2 or 3 (memory read or address calculation).
p4: The number of µops going to port 4 (memory write data).
Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Denormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.

Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

The latencies and throughputs listed below for addition and multiplication using full size YMM registers are obtained only after a warm-up period of a thousand instructions or more. The latencies may be one or two clock cycles longer and the reciprocal throughputs double the values for shorter sequences of code. There is no warm-up effect when vectors are 128 bits wide or less.

List of instruction timings and µop breakdown

Explanation of column headings:

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, y = 256 bit ymm register, same = same register for both operands. m = memory operand, m32 = 32-bit memory operand, etc.

µops fused domain: The number of µops at the decode, rename, allocate and retirement stages in the pipeline. Fused µops count as one.

µops unfused domain: The number of µops for each execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if the sum of the numbers listed under p015 + p23 + p4 exceeds the number listed under µops fused domain. A number indicated as 1+ under a read or write port means a 256-bit read or write operation using two clock cycles for handling 128 bits each cycle. The port cannot receive another read or write µop in the second clock cycle, but a read port can receive an address-calculation µop in the second clock cycle. An x under p0, p1 or p5 means that at least one of the µops listed under p015 can optionally go to this port. For example, a 1 under p015 and an x under p0 and p5 means one µop which can go to either port 0 or port 5, whichever is vacant first. A value listed under p015 but nothing under p0, p1 and p5 means that it is not known which of the three ports these µops go to.

p015: The total number of µops going to port 0, 1 and 5.
p0: The number of µops going to port 0 (execution units).
p1: The number of µops going to port 1 (execution units).
p5: The number of µops going to port 5 (execution units).
p23: The number of µops going to port 2 or 3 (memory read or address calculation).

p4: The number of µops going to port 4 (memory write data).
Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Denormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.
Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

The latencies and throughputs listed below for addition and multiplication using full size YMM registers are obtained only after a warm-up period of a thousand instructions or more. The latencies may be one or two clock cycles longer and the reciprocal throughputs double the values for shorter sequences of code. There is no warm-up effect when vectors are 128 bits wide or less.

Intel Haswell
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, y = 256 bit ymm register, v = any vector register (mmx, xmm, ymm). same = same register for both operands. m = memory operand, m32 = 32-bit memory operand, etc.

µops fused domain: The number of µops at the decode, rename and allocate stages in the pipeline. Fused µops count as one.

µops unfused domain: The total number of µops for all execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if this number is higher than the number under fused domain. Some operations are not counted here if they do not go to any execution port or if the counters are inaccurate.

µops each port: The number of µops for each execution port. p0 means a µop to execution port 0. p01means a µop that can go to either port 0 or port 1. p0 p1 means two µops going to port 0 and 1, respectively.
Port 0: Integer, f.p. and vector ALU, mul, div, branch
Port 1: Integer, f.p. and vector ALU
Port 2: Load
Port 3: Load
Port 4: Store
Port 5: Integer and vector ALU
Port 6: Integer ALU, branch
Port 7: Store address

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Denormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.

Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Integer instructions

Intel Broadwell
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/ x = mmx or xmm register, y = 256 bit ymm register, v = any vector register (mmx, xmm, ymm). same = same register for both operands. m = memory operand, m32 = 32-bit memory operand, etc.

µops fused domain: The number of µops at the decode, rename and allocate stages in the pipeline. Fused µops count as one.

µops unfused domain: The total number of µops for all execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if this number is higher than the number under fused domain. Some operations are not counted here if they do not go to any execution port or if the counters are inaccurate.

µops each port: The number of µops for each execution port. p0 means a µop to execution port 0. p01means a µop that can go to either port 0 or port 1. p0 p1 means two µops going to port 0 and 1, respectively.
Port 0: Integer, f.p. and vector ALU, mul, div, branch
Port 1: Integer, f.p. and vector ALU
Port 2: Load
Port 3: Load
Port 4: Store
Port 5: Integer and vector ALU
Port 6: Integer ALU, branch
Port 7: Store address

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Denormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.

Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Integer instructions

Intel Skylake
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, y = 256 bit ymm register, v = any vector register (mmx, xmm, ymm). m = memory operand, m32 = 32-bit memory operand, etc.

µops fused domain: The number of µops at the decode, rename and allocate stages in the pipeline. Fused µops count as one.

µops unfused domain: The total number of µops for all execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if this number is higher than the number under fused domain. Some operations are not counted here if they do not go to any execution port or if the counters are inaccurate.

µops each port: The number of µops for each execution port. p0 means a µop to execution port 0. p01means a µop that can go to either port 0 or port 1. p0 p1 means two µops going to port 0 and 1, respectively.
Port 0: Integer, f.p. and vector ALU, mul, div, branch
Port 1: Integer, f.p. and vector ALU
Port 2: Load
Port 3: Load
Port 4: Store
Port 5: Integer and vector ALU
Port 6: Integer ALU, branch
Port 7: Store address

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Subnormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.

Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Integer instructions

Intel Skylake-X
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, y = 256 bit ymm register, z = 512 bit zmm register, xy = xmm or ymm register, v = any vector register (mmx, xmm, ymm, zmm). m = memory operand, m32 = 32-bit memory operand, etc.

µops fused domain: The number of µops at the decode, rename, allocate and retire stages in the pipeline. Fused µops count as one.

µops unfused domain: The total number of µops for all execution ports. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if this number is higher than the number under fused domain. Some operations are not counted here if they do not go to any execution port or if the counters are inaccurate.

µops each port: The number of µops for each execution port. p0 means a µop to execution port 0. p01means a µop that can go to either port 0 or port 1. p0 p1 means two µops going to port 0 and 1, respectively.
Port 0: Integer, f.p. and 256 bit vector ALU, mul, div, branch
Port 1: Integer, f.p. and 256 bit vector ALU (re-routed to port 0 for 512-bit vectors)
Port 2: Load
Port 3: Load
Port 4: Store
Port 5: Integer and 512 bit vector ALU
Port 6: Integer ALU, branch
Port 7: Store address

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Subnormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.

Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Intel Coffee Lake
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Instructions with and without V name prefix behave the same unless otherwise noted.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, y = 256 bit ymm register, v = any vector register (mmx, xmm, ymm). m = memory operand, m32 = 32-bit memory operand, etc.

µops fused domain: The number of µops at the decode, rename and allocate stages in the pipeline. Fused µops count as one.

µops unfused domain: The total number of µops for all execution port. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if this number is higher than the number under fused domain. Some operations are not counted here if they do not go to any execution port or if the counters are inaccurate.

µops each port: The number of µops for each execution port. p0 means a µop to execution port 0. p01means a µop that can go to either port 0 or port 1. p0 p1 means two µops going to port 0 and 1, respectively.
Port 0: Integer, f.p. and vector ALU, mul, div, branch
Port 1: Integer, f.p. and vector ALU
Port 2: Load
Port 3: Load
Port 4: Store
Port 5: Integer and vector ALU
Port 6: Integer ALU, branch
Port 7: Store address

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Subnormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.

Reciprocal throughput: The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Integer instructions

Intel Cannon Lake
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction:	Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.
Operands:	i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, z = 512 bit zmm register, xy = xmm or ymm register, v = any vector register (mmx, xmm, ymm, zmm). m = memory operand, m32 = 32-bit memory operand, etc.
µops fused domain:	The number of µops at the decode, rename, allocate and retire stages in the pipeline. Fused µops count as one.
µops unfused domain:	The total number of µops for all execution ports. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if this number is higher than the number under fused domain. Some operations are not counted here if they do not go to any execution port or if the counters are inaccurate.
µops each port:	The number of µops for each execution port. p0 means a µop to execution port 0. p01means a µop that can go to either port 0 or port 1. p0 p1 means two µops going to port 0 and 1, respectively. Port 0: Integer, f.p. and vector ALU, mul, div, branch Port 1: Integer, f.p. and vector ALU Port 2: Load Port 3: Load Port 4: Store Port 5: Integer and vector ALU Port 6: Integer ALU, branch Port 7: Store address
Latency:	This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Subnormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.
Reciprocal throughput:	The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Intel Ice Lake and Tiger Lake
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction:	Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.
Operands:	i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, y = 256 bit ymm register, z = 512 bit zmm register, xy = xmm or ymm register, v = any vector register (mmx, xmm, ymm, zmm). m = memory operand, m32 = 32-bit memory operand, etc.
µops fused domain:	The number of µops at the decode, rename, allocate and retire stages in the pipeline. Fused µops count as one.
µops unfused domain:	The total number of µops for all execution ports. Fused µops count as two. Fused macro-ops count as one. The instruction has µop fusion if this number is higher than the number under fused domain. Some operations are not counted here if they do not go to any execution port or if the counters are inaccurate.
µops each port:	The number of µops for each execution port. p0 means a µop to execution port 0. p01means a µop that can go to either port 0 or port 1. p0 p1 means two µops going to port 0 and 1, respectively. Port 0: Integer, f.p. and 256 bit vector ALU, mul, div, branch Port 1: Integer, f.p. and 256 bit vector ALU (re-routed to port 0 for 512-bit vectors) Port 23: Load Port 49: Store Port 78: Store address Port 5: Integer and 512 bit vector ALU Port 6: Integer ALU, branch
Latency:	This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Where hyperthreading is enabled, the use of the same execution units in the other thread leads to inferior performance. Subnormal numbers, NAN's and infinity do not increase the latency. The time unit used is core clock cycles, not the reference clock cycles given by the time stamp counter.
Reciprocal throughput:	The average number of core clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Intel Pentium 4

List of instruction timings and μop breakdown

This list is measured for a Pentium 4, model 2. Timings for model 3 may be more like the values for P4E, listed on the next sheet

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, xmm = 128 bit xmm register, sr = segment register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc.

μops: Number of μops issued from instruction decoder and stored in trace cache.

Microcode: Number of additional μops issued from microcode ROM.

Latency: This is the delay that the instruction generates in a dependency chain if the next dependent instruction starts in the same execution unit. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latency of moves to and from memory cannot be measured accurately because of the problem with memory intermediates explained above under "How the values were measured".

Additional latency: This number is added to the latency if the next dependent instruction is in a different execution unit. There is no additional latency between ALU0 and ALU1.

Reciprocal throughput: This is also called issue latency. This value indicates the number of clock cycles from the execution of an instruction begins to a subsequent independent instruction can begin to execute in the same execution subunit. A value of 0.25 indicates 4 instructions per clock cycle in one thread.

Port: The port through which each μop goes to an execution unit. Two independent μops can start to execute simultaneously only if they are going through different ports.

Execution unit: Use this information to determine additional latency. When an instruction with more than one μop uses more than one execution unit, only the first and the last execution unit is listed.

Execution subunit: Throughput measures apply only to instructions executing in the same subunit.

Instruction set   Indicates the compatibility of an instruction with other 80x86 family microprocessors. The instruction can execute on microprocessors that support the instruction set indicated.

Integer instructions

Notes:

a) Add 1 µop if source is a memory operand.

b) Uses an extra µop (port 3) if SIB byte used. A SIB byte is needed if the memory operand has more than one pointer register, or a scaled index, or ESP is used as base pointer.

c) Add 1 µop if source or destination, but not both, is a high 8-bit register (AH, BH, CH, DH).

d) Has (false) dependence on the flags in most cases.

e) Not available on PMMX

q) Latency is 12 in 16-bit real or virtual mode, 24 in 32-bit protected mode.

Notes:

e)	Not available on PMMX
f)	The latency for FLDCW is 3 when the new value loaded is the same as the value of the control word before the preceding FLDCW, i.e. when alternating between the same two values. In all other cases, the latency and reciprocal throughput is 143.
g)	Latency and reciprocal throughput depend on the precision setting in the F.P. control word. Single precision: 23, double precision: 38, long double precision (default): 43.
h)	Throughput of FP-MUL unit is reduced during the use of the FP-DIV unit.
i)	Takes 6 µops more and 40-80 clocks more when XMM registers are disabled.

h)   Throughput of FP-MUL unit is reduced during the use of the FP-DIV unit.

k)   It may be advantageous to replace this instruction by two 64-bit moves.

Intel Pentium 4 w. EM64T (Prescott)
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate constant, r = any register, r32 = 32-bit register, etc., mm = 64 bit mmx register, xmm = 128 bit xmm register, sr = segment register, m = any memory operand including indirect operands, m64 means 64-bit memory operand, etc., mabs = memory operand with 64-bit absolute address.

µops: Number of µops issued from instruction decoder and stored in trace cache.

Microcode: Number of additional µops issued from microcode ROM.

Latency: This is the delay that the instruction generates in a dependency chain if the next dependent instruction starts in the same execution unit. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's, infinity and exceptions increase the delays. The latency of moves to and from memory cannot be measured accurately because of the problem with memory intermediates explained above under "How the values were measured".

Additional latency: This number is added to the latency if the next dependent instruction is in a different execution unit. There is no additional latency between ALU0 and ALU1.

Reciprocal throughput: This is also called issue latency. This value indicates the number of clock cycles from the execution of an instruction begins to a subsequent independent instruction can begin to execute in the same execution subunit. A value of 0.25 indicates 4 instructions per clock cycle in one thread.

Port: The port through which each µop goes to an execution unit. Two independent µops can start to execute simultaneously only if they are going through different ports.

Execution unit: Use this information to determine additional latency. When an instruction with more than one µop uses more than one execution unit, only the first and the last execution unit is listed.

Execution subunit: Throughput measures apply only to instructions executing in the same subunit.

Instruction set   Indicates the compatibility of an instruction with other 80x86 family microprocessors. The instruction can execute on microprocessors that support the instruction set indicated.

MONITOR										(sse3)	
MWAIT										(sse3)	

Notes:

a)	Add 1 µop if source is a memory operand.
b)	Uses an extra µop (port 3) if SIB byte used.
c)	Add 1 µop if source or destination, but not both, is a high 8-bit register (AH, BH, CH, DH).
d)	Has (false) dependence on the flags in most cases.
e)	Not available on PMMX
l)	Move accumulator to/from memory with 64 bit absolute address (opcode A0 - A3).

m) Not available in 64 bit mode.

n) Not available in 64 bit mode on some processors.

o) MOVSX uses an extra µop if the destination register is smaller than the biggest register size available. Use a 32 bit destination register in 16 bit and 32 bit mode, and a 64 bit destination register in 64 bit mode for optimal performance.

p) LEA with a direct memory operand has 1 µop and a reciprocal throughput of 0.25. This also applies if there is a RIP-relative address in 64-bit mode. A sign-extended 32-bit direct memory operand in 64-bit mode without RIP-relative address takes 2 µops because of the SIB byte. The throughput is 1 in this case. You may use a MOV instead.

q) These values are measured in 32-bit mode. In 16-bit real mode there is 1 microcode µop and a reciprocal throughput of 17.

Notes:

e) Not available on PMMX

f) The latency for FLDCW is 3 when the new value loaded is the same as the value of the control word before the preceding FLDCW, i.e. when alternating between the same two values. In all other cases, the latency and reciprocal throughput is > 100.

g) Latency and reciprocal throughput depend on the precision setting in the F.P. control word. Single precision: 32, double precision: 40, long double precision (default): 45.

h) Throughput of FP-MUL unit is reduced during the use of the FP-DIV unit.

i) Takes fewer microcode µops when XMM registers are disabled, but the throughput is the same.

Notes:

a)   Add 1 µop if source is a memory operand.

j)   Reciprocal throughput is 1 for 64 bit operands, and 2 for 128 bit operands.

k)   It may be advantageous to replace this instruction by two 64-bit moves or LD-DQU.

Notes:

a)   Add 1 µop if source is a memory operand.

h)   Throughput of FP-MUL unit is reduced during the use of the FP-DIV unit.

k)   It may be advantageous to replace this instruction by two 64-bit moves or LDDQU.

Intel Atom

List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Instruction name. cc means any condition code. For example, Jcc can be JB, JNE, etc.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, mm/x = mmx or xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.

µops: The number of µops from the decoder or ROM.

Unit: Tells which execution unit is used. Instructions that use the same unit cannot execute simultaneously.

ALU0 and ALU1 means integer unit 0 or 1, respectively.

ALU0/1 means that either unit can be used. ALU0+1 means that both units are used.

Mem means memory in/out unit.

FP0 means floating point unit 0 (includes multiply, divide and other SIMD instructions).

FP1 means floating point unit 1 (adder).

MUL means multiplier, shared between FP and integer units.

DIV means divider, shared between FP and integer units.

np means not pairable: Cannot execute simultaneously with any other instruction.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.

Reciprocal throughput: The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

Intel Silvermont
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, m = memory, m32 = 32-bit memory operand, etc.

µops: The number of µops from the decoder or ROM. A µop that goes to multiple units is counted as one.

Unit: Tells which execution unit is used. Instructions that use the same unit cannot execute simultaneously.

IP0 and IP1 means integer port 0 or 1 and their associated pipelines

IP0/1 means that either integer unit can be used.

IP0+1 means that the µop is split in two, using both units.

Mem means memory execution cluster

FP0 means floating point port 0 (includes multiply, divide, convert and shuffle).

FP1 means floating point port 1 (adder).

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.

Reciprocal throughput: The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread. Delays in the decoders are included in the latency and throughput timings. Values of 4 or more are often caused by bottlenecks in the decoders and microcode ROM rather than the execution units.

Intel Goldmont
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, v = mmx or xmm vector register, m = memory, m32 = 32-bit memory operand, etc.

µops: The number of µops from the decoder or ROM. A µop that goes to multiple units is counted as one.

Unit: Tells which execution unit is used. Instructions that use the same unit cannot execute simultaneously.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.

Reciprocal throughput: The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread. Delays in the decoders are included in the latency and throughput timings. Values of 4 or more are often caused by bottlenecks in the decoders and microcode ROM rather than the execution units.

List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, v = mmx or xmm vector register, m = memory, m32 = 32-bit memory operand, etc.

µops: The number of µops from the decoder or ROM. A µop that goes to multiple units is counted as one.

Unit: Tells which execution unit is used. Instructions that use the same unit cannot execute simultaneously.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.

Reciprocal throughput: The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread. Delays in the decoders are included in the latency and throughput timings. Values of 4 or more are often caused by bottlenecks in the decoders and microcode ROM rather than the execution units.

Intel Tremont
List of instruction timings and µop breakdown

Explanation of column headings:

Instruction:	Name of instruction. Multiple names mean that these instructions have the same data.
Operands:	i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, v = mmx or xmm vector register, m = memory, m32 = 32-bit memory operand, etc.
µops:	The number of µops from the decoder or ROM. A µop that goes to multiple units is counted as one.
Unit:	Tells which execution unit is used. Instructions that use the same unit cannot execute simultaneously.
Latency:	This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.
Reciprocal throughput:	The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread. Delays in the decoders are included in the latency and throughput timings. Values of 4 or more are often caused by bottlenecks in the decoders and microcode ROM rather than the execution units.

Intel Knights Landing

List of instruction timings and µop breakdown

Explanation of column headings:

Instruction: Name of instruction. Multiple names mean that these instructions have the same data. Instructions with or without V name prefix behave the same unless otherwise noted.

Operands: i = immediate data, r = register, mm = 64 bit mmx register, x = 128 bit xmm register, mm/x = mmx or xmm register, y = 256 bit ymm register, z = 512 bit zmm register, v = any vector register (mmx, xmm, ymm, zmm), k = mask register. same = same register for both operands. m = memory operand, m32 = 32-bit memory operand, etc.

µops: The number of µops from the decoder or ROM. A µop that goes to multiple units is counted as one.

Unit: Tells which execution unit is used. Instructions that use the same unit cannot execute simultaneously.

IP0 and IP1 means integer port 0 or 1 and their associated pipelines

IP0/1 means that either integer unit can be used.

IP0+1 means that the µop is split in two, using both units.

Mem means memory execution cluster

FP0 means floating point port 0 (includes multiply, divide, convert and shuffle).

FP1 means floating point port 1.

Latency: This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.

Some instructions have a range of latencies. For example VPSHUFD has a latency of 3-6. The short latency is measured in a chain of similar instructions. The long latency is measured when the input comes from an instruction of a different type and the output goes to an instruction of a different type, for example a move instruction. The long latency will apply in most cases. Division and some square root instructions have latencies that depend on the values of the operands.

Reciprocal throughput: The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread. Delays in the decoders are included in the latency and throughput timings. Values of 4 or more are often caused by bottlenecks in the decoders and microcode ROM rather than the execution units.

VIA Nano 2000 series
List of instruction timings and µop breakdown

Explanation of column headings:

Operands:	i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, mm/x = mmx or xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.
µops:	The number of micro-operations from the decoder or ROM. Note that the VIA Nano 2000 processor has no reliable performance monitor counter for µops. Therefore the number of µops cannot be determined except in simple cases.
Port:	Tells which execution port or unit is used. Instructions that use the same port cannot execute simultaneously.

	I1:	Integer add, Boolean, shift, etc.
	I2:	Integer add, Boolean, move, jump.
	I12:	Can use either I1 or I2, whichever is vacant first.
	MA:	Multiply, divide and square root on all operand types.
	MB:	Various Integer and floating point SIMD operations.
	MBfadd:	Floating point addition subunit under MB.
	SA:	Memory store address.
	ST:	Memory store.
	LD:	Memory load.

Latency:	This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are presumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar delay.
	Note: There is an additional latency for moving data from one unit or subunit to another. A table of these latencies is given in manual 3: "The microarchitecture of Intel, AMD and VIA CPUs". These additional latencies are not included in the listings below where the source and destination operands are of the same type.
Reciprocal throughput:	The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

REP XSHA1		3 clock per byte
REP XSHA256		4 clock per byte

VIA Nano 3000 series
List of instruction timings and µop breakdown

Explanation of column headings:

Operands:	i = immediate data, r = register, mm = 64 bit mmx register, xmm = 128 bit xmm register, mm/x = mmx or xmm register, sr = segment register, m = memory, m32 = 32-bit memory operand, etc.
µops:	The number of micro-operations from the decoder or ROM. Note that the VIA Nano 3000 processor has no reliable performance monitor counter for µops. Therefore the number of µops cannot be determined except in simple cases.
Port:	Tells which execution port or unit is used. Instructions that use the same port cannot execute simultaneously.

	I1:	Integer add, Boolean, shift, etc.
	I2:	Integer add, Boolean, move, jump.
	I12:	Can use either I1 or I2, whichever is vacant first.
	MA:	Multiply, divide and square root on all operand types.
	MB:	Various Integer and floating point SIMD operations.
	MBfadd:	Floating point addition subunit under MB.
	SA:	Memory store address.
	ST:	Memory store.
	LD:	Memory load.

Latency:	This is the delay that the instruction generates in a dependency chain. The numbers are minimum values. Cache misses, misalignment, and exceptions may increase the clock counts considerably. Floating point operands are pre-sumed to be normal numbers. Denormal numbers, NAN's and infinity increase the delays very much, except in XMM move, shuffle and Boolean instructions. Floating point overflow, underflow, denormal or NAN results give a similar de-lay.
	Note: There is an additional latency for moving data from one unit or subunit to another. A table of these latencies is given in manual 3: "The microarchitecture of Intel, AMD and VIA CPUs". These additional latencies are not included in the listings below where the source and destination operands are of the same type.
Reciprocal throughput:	The average number of clock cycles per instruction for a series of independent instructions of the same kind in the same thread.

VIA-specific instructions

Instruction	Conditions	Clock cycles, approximately
XSTORE	Data available	160-400 clock giving 8 bytes
XSTORE	No data available	50-80 clock giving 0 bytes
REP XSTORE	Quality factor = 0	1300 clock per 8 bytes
REP XSTORE	Quality factor > 0	5455 clock per 8 bytes
REP XCRYPTECB	128 bits key	15 clock per 16 bytes
REP XCRYPTECB	192 bits key	17 clock per 16 bytes
REP XCRYPTECB	256 bits key	18 clock per 16 bytes
REP XCRYPTCBC	128 bits key	29 clock per 16 bytes
REP XCRYPTCBC	192 bits key	33 clock per 16 bytes
REP XCRYPTCBC	256 bits key	37 clock per 16 bytes
REP XCRYPTCTR	128 bits key	23 clock per 16 bytes
REP XCRYPTCTR	192 bits key	26 clock per 16 bytes
REP XCRYPTCTR	256 bits key	27 clock per 16 bytes
REP XCRYPTCFB	128 bits key	29 clock per 16 bytes

REP XCRYPTCFB	192 bits key		33 clock per 16 bytes
REP XCRYPTCFB	256 bits key		37 clock per 16 bytes
REP XCRYPTOFB	128 bits key		29 clock per 16 bytes
REP XCRYPTOFB	192 bits key		33 clock per 16 bytes
REP XCRYPTOFB	256 bits key		37 clock per 16 bytes
REP XSHA1			5 clock per byte
REP XSHA256			5 clock per byte
